

PersonalAIStation — "The Digital Self"

A research project on personal continuity: a body, a memory, time-sliced selves, and a legacy for descendants

Author and founder: Alexander D. Budanov

Contacts: it@alexbudanov.ru · Telegram @alexandr_budanov_it

GitHub (public concept and this document): <https://github.com/MyFirstProd/PAIStation>

Author's channel (projects, hardware, work in progress): https://t.me/error404_engineer_not_found

Document date: October 6, 2026 · Version 1.1

Status: working prototype running at the founder's home; research program described below

The ask: \$250,000 over 12 months in three tranches against verifiable milestones (Section 12)

If you have five minutes: Sections 1, 8, 11, 12 and 14.

1. The idea in one paragraph

We are building a local system that lives beside a person for years: it sees through a motorized camera, listens, remembers only what the person has consented to, stores every event with its source and time, and from that corpus forms **dated slices of a personality** — like growth rings in a tree. The 2026 slice and the 2036 slice are two different "selves" that can be compared, restored and questioned. The horizon goal is not a chatbot "in Alexander's style" but an honest, verifiable copy of memory, manner and values that a person leaves to children and grandchildren: something they can talk to, ask for advice, and hear in the original voice. We call this the **Theseus experiment**: if you replace one plank a year, at what point does the ship stop being the same ship — and can that be measured?

2. Why now

- Local language models now run on a consumer GPU with quality sufficient for live dialogue. Personal data no longer has to leave the house.
- The first complete connectome of an adult fruit-fly brain has been published (FlyWire, 2024: 139,255 neurons, ~50 million synapses) along with executable models built on it. This opens a real rather than fantastical path: first learn to move sensorimotor decisions onto a scanned fly brain, then onto more complex organisms, and be ready for the moment human brain scans exist.
- People already leave terabytes of photos and messages behind, yet none of it can **answer**. The gap between "archive" and "interlocutor" is empty. Whoever fills it honestly — with consent, with sources, without forged authorship — sets the standard for the digital era.

3. How this differs from "digital avatars"

Common approach	Our approach
Upload chat logs into a cloud model	Everything local: model, archive, voice, biometrics. Cloud only by explicit choice
The model "plays the role" of a person	Every statement rests on a recorded event [event:N] or a confirmed fact [fact:N]; a fabricated reference is rejected by code
Personality is the result of a prompt	Personality is the result of consent, source verification, a correction loop and a signed, dated slice
One static avatar	Yearly slices, restorable as separate copies, with no leakage of the "future" into the past
Anyone can talk "as" the person	The copy does not activate on a stranger's voice and does not answer outsiders on the owner's behalf
Text and only text	A body: camera on a pan/tilt turret, microphone, owner recognition by face and voice, timestamped vision events

4. What already works (verifiable, October 2026)

These are not slides. The public part (concept, Mind ABI, Fly Lab, roadmap) is on GitHub: <https://github.com/MyFirstProd/PAIStation>. Working code, tests and reports live in the author's private repository, available under NDA; the numbers below come from the latest run.

Body - Pan/tilt turret: Arduino Uno R3, two MG996R servos, working range 5–175° on both axes, smooth acceleration profile (50°/s²) as the primary safety parameter; calibration in EEPROM; FHD USB camera; Razer Seiren Mini microphone. - Software face tracking with jitter suppression (EMA) and protection against instant loss of privileges when the head turns. - Local owner recognition by face and voice; the result is always probabilistic and carries `verified: false` — recognition is **never** treated as proof of authorship or consent. - **Hands and keyboard**. The system already has a computer-control loop: code, browser, Windows desktop. It works **with a mouse and keyboard the way a human does** — sees the screen, moves the cursor, types — not through hidden APIs; irreversible actions require confirmation. 13 of 20 acceptance criteria for this loop are closed. In the memory profile the hands are deliberately disabled so that memory is finished first; later the copy will be able to work at a computer the way the owner did — with his sequence of actions and his habits.

Memory - Encrypted event archive (SQLite, Windows DPAPI): each event is an envelope with sensor time, receipt time, timing quality and provenance. Idempotent, protected against duplicates and reordering; source outages are visible. - Conversational memory with sources: the model receives only trusted excerpts with identifiers; references are checked after the answer. - **Facts with validity periods**: "Remember / Correct / Forget" run without the model; a correction never overwrites the old value but builds a version chain. Statements that look like passwords or keys are rejected. - **Speaker attribution** on every heard utterance: typed, voice-matched against a reference (with similarity), or "not analyzed". - Verbatim recall without the model ("Recall: ..." → quotes with time and source). - Time windows in questions ("yesterday", "last week", "3 days ago").

Slices (tree rings) - A full encrypted archive slice with manifest, integrity verification and restore **into a separate copy** with all sensors disabled. A real archive of 3,902 records has been saved and restored; the live archive stayed untouched. - A "future leak" check: a fact added after the slice must not appear in the restored copy — this is an automated test.

Quality and engineering gates - 2,211 automated tests; static analysis and type checks clean. - Gate M0 closed (replay with duplicates, reordering, clock jumps, audio outage, restart — 23 named checks). - A **one-hour memory trial** harness is built: 6 stages, 20 facts, 4 corrections, guest utterances, slice and restart, 30 deferred questions (facts / corrections / time / "no evidence" / authorship / vision), threshold 27/30 plus hard requirements: zero fabricated references, no guest words attributed to the owner. Synthetic run: 30/30; the live hour on a real microphone is the immediate next step. - Mind ABI v0 — a protocol separating six concepts: identity, memory, cognitive state, model/connectome, embodiment, continuity log. It lets a language model and a neural brain model attach to the same body and the same memory as interchangeable "thinking" modules.

What is **not** done, stated plainly: the live one-hour and 24-hour runs, portable restore onto another machine, episodic consolidation, training of a personal adapter, and any fly neural backend.

5. How the system learns and listens

1. **The body observes.** The turret camera keeps the owner in frame; the microphone records with timestamps. Every frame and phrase becomes an event with source, time and uncertainty. No model rewrites observations with its own descriptions.
2. **Consent comes before recording.** Sources are enabled explicitly by the owner; revoking consent cancels operations already in flight. On first launch every source is off.
3. **Attribution.** Each utterance carries who probably said it. A guest's voice never becomes "the owner's opinion".
4. **The companion-interviewer.** A second entity on the same corpus — not a copy but a conversational partner that asks at the right moment: "you mentioned your grandfather — tell me about him." The answer enters the corpus whole, with audio. Declining is a normal answer; the topic is not pressed.
5. **Facts and corrections.** The person says "Remember", "Correct", "Forget" — the system keeps a version chain without erasing history. This is how a fact acquires a validity period: "in 2026 I loved X; from 2029 I did not."
6. **Episodes and consolidation (next stage).** Episodes with participants and source references are built from the event stream; overnight consolidation produces derived records, never replacements for evidence.
7. **The slice.** Periodically a signed, dated slice is created: memory, style, voice corpus, the chosen model and its parameters, limits of representation. The slice is restorable as a separate copy.
8. **Training comes last.** A personal adapter (speech manner, reactions) is trained only once the data has passed quality checks and independent tests exist. Weights never replace sources inside a slice.

6. Research program: from fly to human

This is the main reason the project deserves funding as research rather than as an app.

Hypothesis. If the *mechanism of thinking* (language model, neural simulation, anything) is separated from the *personality* (memory, identity, embodiment, continuity in time), the same memory and the same body can be attached to different mechanisms — and we can measure what is preserved.

Stage A. A full fly connectome drives the body. Open data (FlyWire, MaleCNS) and open executable kernels (DOOMFLY, Shiu et al., Flyvis) make an honest experiment possible: camera input changes the neural network's state, neuron output turns the turret, the turn changes the next frame. No language model steers in secret. Criteria are declared in advance: $\geq 90\%$ direction accuracy on held-out scenes, $p_{95} \leq 100$ ms, mandatory controls — blinded input, silenced readout, shuffled connectivity. If the neural path contributes nothing measurable under ablation, that is an honest negative result.

Stage B. Hybrid. Through Mind ABI the neural controller proposes where to look, the language model proposes what to say, and a host arbiter decides. Four conditions are compared: baseline controller only, neurons only, model only, hybrid.

Stage C. Transferring decisions. Part of emotional-behavioral reactions (orienting, alarm, interest, avoidance) are sensorimotor circuits that a fly has too. We test whether such reactions can be moved out of the language model into a scanned brain while memory and speech stay outside. This is the first rehearsal of the central question: **what remains "me" if the mechanism is replaced.**

Stage D. Readiness for a human scan. A complete human connectome does not exist today, and we do not promise one. But all of the engineering — the protocol, the continuity log, slices, the separation of memory from mechanism, consent ethics — is built so that when such data appears we already have proven infrastructure, a corpus spanning years and an evaluation method. Then an "emotionally remembering copy" becomes an engineering task, not a fantasy.

Every claim in this section is a working hypothesis with pre-declared failure criteria. We do not use the phrase "mind upload" as a fact.

7. Intermediate stage: digital immortality for a pet

A dog or a cat is the ideal first "personality" for the method:

- the same sensors (turret camera, microphone), the same events, the same slices;
- an animal's behavior is easier to measure than a human's, and the ethical stakes are lower;
- the emotional value for a family is enormous while expectations are more honest: nobody expects philosophy from a copy of a dog — they expect recognition, reaction, voice;
- the pet is exactly where transferring sensorimotor reactions onto neural models (Stage C) is convenient to test.

It is at once a scientific test bed and the first understandable product that can be shown to families before the human copy matures.

8. Where this applies today: slices of significant people and a pattern scanner

The same machine that keeps one person's memory for his family solves two problems any business understands today. The core does not change — only whose memory it is and who asks the questions.

8.1 A slice of a significant person: leader, founder, master of a craft

The experience of a strong leader or a rare professional — a surgeon, a trial lawyer, a design engineer, a trader, a chef, a teacher, an investigator — usually leaves with them. Procedures and knowledge bases capture *what* to do, not *how they thought*: which signals they read first, where they stumbled, when and why they changed their mind.

A slice works differently:

- a year alongside the person: camera, microphone, and a companion-interviewer that asks at the right moment, "why did you decide it that way?";
- every judgment is recorded with time and source; corrections do not erase but build a chain: "in 2026 he held X, from 2028 — Y, and here is why";
- the result is a dated "slice 2026" of that person. A successor, a new hire, the family can talk to it. It answers only from evidence and honestly says "I never spoke about that."

Who needs it: family businesses handing the company to heirs; boards when a founder steps away; clinics, law and engineering firms as a "mentor from the record" for the young; the person himself, as a mirror of his own decisions year by year. The slice belongs to the person and passes under his charter; it is not workplace surveillance.

The first "significant person" could be the investor himself: a yearly ring of his memory and his way of deciding — for his family and his business.

8.2 A pattern scanner: checking words against one's own history, surfacing lies

Because every statement is stored with time, source and a version chain, the system can do what no chat can: compare a person's new statement with what that same person said before, and show the discrepancy — with links to both records.

- "In March you said the deal closed on the 12th; today you say the 20th. Here are both records."
- "For three years this person never changed his position on X; today he did — here is where, and after what."
- "Across five years of records his priorities shift like this — here is the trajectory by year."

This is not a polygraph and not "lie detection from a face." The system reads no emotions and issues no verdict. It finds contradictions, pattern breaks and timing mismatches in recorded information and presents the evidence to the human who decides: a judge or arbitrator reconciling testimony, an investigator, an investor doing due diligence on founders and counterparties, an editor fact-checking, a hiring manager — and, in the personal version, the person himself as an honest mirror. The condition never changes: the recorded party has consented or the information is public, and the final word belongs to a human.

9. Ethics built into code, not into a policy page

- Recording only with explicit consent; revocation takes effect immediately.
- Recognition ≠ authorship ≠ permission. Three different things, three fields.
- The copy does not answer outsiders on the person's behalf and does not activate on a stranger's voice.

- Every answer of the copy rests on a source; "I don't know" is a mandatory honest answer.
- A slice is signed and dated; a "new version" is never silently presented as "the same person" — the transition is recorded in the continuity log.
- How the copy passes to descendants (medium, conditions, who may activate it) is a separate charter the family approves during the person's lifetime.

10. Roadmap (24 months)

Period	Milestone	What it proves
0–3 mo	Live one-hour and 24-hour memory runs; portable slice restore	Memory survives restarts, a full day and a change of machine
3–6 mo	Episodes and consolidation; the founder's first yearly slice ("ring 2026")	"What happened and what changed" can be asked with sources
3–9 mo	Fly Lab Stage A: full fly connectome drives a virtual, then a real turret	The neural loop contributes measurably (or honestly does not)
6–12 mo	Personal adapter for speech manner and voice with independent tests	The copy "sounds like" without losing source honesty
9–15 mo	"Digital pet" pilot in 3–5 families	The method transfers to another personality; first product
12–18 mo	Mind ABI hybrid (Stage B) and reaction transfer (Stage C)	What is preserved when the mechanism is replaced
18–24 mo	Copy pilot with 5–10 volunteers, legacy transfer charter, publications	Reproducibility, an ethical standard, a scientific result
18–24 mo	Return of the "hands": the copy works at a computer with mouse and keyboard under supervision, reproducing the owner's habits	Personality shows not only in words but in actions

11. Company and team

Today the project is one person. For research with volunteers, families and other people's data that is not enough — not for engineering reasons, but for legal and ethical ones. With this round the project is incorporated and a small team is assembled; the jurisdiction (US or another convenient for the investor) is agreed in the first conversation.

Role	Why this role specifically	Status
Founder — lead and principal engineer	Architecture, memory, body, Fly Lab, demos	In place; moves to the project full time
Second engineer (ML / embedded)	Fly Lab and neural models, body kits for the pilots; the founder stops being a single point of failure	Missing — hired in the first 3 months

Role	Why this role specifically	Status
Lawyer (data, consent, IP)	Legacy transfer charter, agreements with volunteers and families, open license for the core with closed personal data, incorporation	Missing — on retainer
Project ethics specialist	An independent voice with veto power over experiments with people and pets, consent protocols, a public ethics report every six months	Missing — contract; accountable to the investor and the founder at once
Accountant / finance	Bookkeeping, tranche reporting, taxes in two jurisdictions	Missing — outsourced
Scientific advisory board (2–3 neuroscientists and AI researchers)	Review of the Fly Lab method and the pre-registered failure criteria	Formed through the investor's community

12. Budget: \$250,000 over 12 months

Today the project is built by one person, in the evenings, on a consumer PC with an RTX 3060 (12 GB) and a hard drive. That is enough for a prototype; for research it is not: the fly neural model, adapter training, 24-hour video/audio recording, several personalities at once and other people's data hit the limits of GPU, disk, people and law.

Amounts are in US dollars; ruble items are converted at the Bank of Russia rate for October 6, 2026 (84.93 ₽/\$, rounded to 85). Ruble items are actual obligations and Moscow market rates; dollar items are engineering estimates with headroom, not vendor quotes.

12.1 Allocation

Area	Item	Amount	Note
People — \$149,000 (60%)	Closing the founder's existing debts	\$8,000	700,000 ₽; one-time, documented
	Founder salary, full time	\$71,000	500,000 ₽/month × 12. The founder currently earns 250,000 ₽/month on outside work; the 2× rate buys out all other contracts
	Second engineer (ML / embedded)	\$40,000	≈ 280,000 ₽/month × 12, Moscow senior-level market
	Lawyer, retainer	\$12,000	Incorporation, legacy charter, participant agreements, licenses
	Ethics specialist, contract	\$10,000	Consent protocols, veto power, two public reports
	Accountant, incorporation, banking, compliance	\$8,000	Two jurisdictions, tranche reporting

Area	Item	Amount	Note
Equipment and compute — \$43,000 (17%)	Workstation: 1× RTX PRO 6000 (96 GB) or 2× RTX 5090, 128–256 GB RAM	\$22,000	Fly neural model + language model + adapter training simultaneously
	Storage 40–60 TB (RAID, encrypted) + offline backup	\$6,000	≈ 2.8 GB/day for audio alone; video an order of magnitude more
	3 "body" kits (turret on industrial servos, camera, microphone, controller)	\$6,000	Pet pilot and volunteers
	UPS, network, rack	\$3,000	Continuous 24/7 recording
	Cloud GPUs for experiments without personal data	\$6,000	Neural simulation runs on different hardware
Premises — \$41,000 (16%)	Lab rent 30–50 m ² , Moscow	\$35,000	≈ 250,000 ₺/month × 12; sound insulation, rack, 2–3 stands, receiving families
	Fit-out, sound insulation, electrical	\$6,000	One-time
Pilots and science — \$8,000 (3%)	Compensation for families and volunteers, consumables	\$5,000	"Digital pet" pilot, first volunteers
	Publications, conferences, open documentation	\$3,000	Fly Lab, Mind ABI, ethics report
Reserve — \$9,000 (4%)	Contingency: exchange rate, GPU prices, hardware replacement	\$9,000	Spent only with notice to the investor
Total		\$250,000	≈ 21.25 M ₺

12.2 Tranches against milestones

The money is not advanced for a year; it is released against results. Every milestone is a test, a report and a dated slice that can be verified.

Tranche	When	Amount	What is shown before release
1	Start	\$110,000	Signed plan and criteria; debts closed; workstation and storage purchased; engineer vacancy opened; incorporation started
2	Month 4	\$70,000	Live one-hour and 24-hour memory runs passed at the pre-announced threshold; the founder's "ring 2026" created and restored on another machine; company, lawyer, ethics specialist and engineer in place
3	Month 9	\$70,000	Fly Lab Stage A completed against published criteria (an honest negative result counts); "digital pet" pilot running in the first families; first public ethics report

If a milestone is missed, the tranche is not released and a report on the causes is published — that is part of the method, not an exception to it.

13. Why this deserves funding

Not for quick profit. For what grows out of the ideas:

- **A standard for honest digital memory.** Consent, source, time, attribution, slices — this is a protocol every "digital twin" product will need. We are building it first and in the open.
- **Mind ABI as a bridge between AI and neuroscience.** One contract to which a language model, a fly connectome and, one day, a human scan can attach.
- **The Theseus experimental method.** A measurable answer to "what remains a personality when the mechanism is replaced" is a scientific result that does not exist yet.
- **Legacy as a new category.** Families gain something history never had: the ability to ask a great-grandfather for advice in his own voice, with his own memory, and with an honest marker where the evidence ends.
- **Slices of significant people and the pattern scanner** (Section 8) — two applications a business understands today, on the same core and under the same consent rules.

Commercial paths exist and are obvious — a legacy service for families, a "digital pet" product, slices of leaders and professionals for companies, a pattern scanner for due diligence and law, licensing the memory core to companion developers — but they follow the research rather than lead it.

14. What we ask

1. **\$250,000 over 12 months** in three tranches against milestones (Section 12), for the roadmap in Section 10 and the team in Section 11.
2. Access to the developer and neuroscience community for review of the Fly Lab methodology.
3. The right to keep the memory core and the Mind ABI protocol open; the participants' personal data remains their property, always.
4. A direct conversation with the founder before a decision: a live demo of the working system (camera, memory, slice) takes 30 minutes and says more than any document.

The project is run transparently: every milestone is a test, a report and a dated slice that can be verified — not a presentation.

Author and contacts

Alexander D. Budanov — founder and, as of today, sole developer of the project.
